

# The Optimal Design of Climate Agreements

## Inequality, Trade, and Incentives for carbon policy

WORK IN PROGRESS

*Thomas Bourany*

THE UNIVERSITY OF CHICAGO

*Joint workshop - Capital Theory / Trade-Spatial*

March 2024

# Introduction

- ▶ Fighting climate change requires implementing ambitious carbon reduction policies
    - However, one of the sources of international inaction is the “free-riding problem”
    - Implementing taxation of carbon and fossil fuels is costly for individual countries
    - Moreover, such climate policy redistributes across countries through
      - (i) energy markets (ii) change in climate, and (iii) reallocation of activity through trade
  - ▶ One proposal to solve climate inaction is the idea of “climate club” – Nordhaus (2015)
    - Climate coalitions taxing carbon are inherently “unstable”
    - Trade sanctions need to be imposed on non-participants to sustain a “club” and reduce emissions meaningfully
- ⇒ How can we design an optimal climate agreement that implements the optimal energy taxation in the presence of inequality and policy constraints ?

## Introduction – this project

- ▶ Trade-off between intensive margin and extensive margin :
  - Climate agreement with a small number of countries, higher tax and large emissions reductions for members of the agreements
  - Extensive climate agreements with a large number of countries but lower optimal tax to accommodate participation constraints
  - Trade tariffs/sanctions for non-members are crucial for the stability of the agreement

## Introduction – this project

- ▶ Trade-off between intensive margin and extensive margin :
  - Climate agreement with a small number of countries, higher tax and large emissions reductions for members of the agreements
  - Extensive climate agreements with a large number of countries but lower optimal tax to accommodate participation constraints
  - Trade tariffs/sanctions for non-members are crucial for the stability of the agreement
- ▶ Build an Integrated Assessment Model (IAM) with heterogeneous countries & trade to :
  - Evaluate the welfare costs of global warming and solve optimal carbon policy
  - Analyze the strategic implications of joining climate agreements
  - Design the optimal size of the climate club

## Introduction – this project

- ▶ Trade-off between intensive margin and extensive margin :
  - Climate agreement with a small number of countries, higher tax and large emissions reductions for members of the agreements
  - Extensive climate agreements with a large number of countries but lower optimal tax to accommodate participation constraints
  - Trade tariffs/sanctions for non-members are crucial for the stability of the agreement
- ▶ Build an Integrated Assessment Model (IAM) with heterogeneous countries & trade to :
  - Evaluate the welfare costs of global warming and solve optimal carbon policy
  - Analyze the strategic implications of joining climate agreements
  - Design the optimal size of the climate club
- ▶ Preview of the results :
  - For unilateral deviation, i.e. Nash-equilibrium climate agreement, second-best world optimal policy is sustainable : high carbon tax, high tariffs, participation of the entire world
  - Optimal agreements robust to “subcoalition deviation” depend on the trade-off between (i) gains from trade, (ii) climate damage and (iii) distortionary effects of the carbon tax

# Literature

## ► Climate change & optimal carbon taxation

- RA model : Nordhaus DICE (1996-), Weitzman (2014), Golosov et al (2014)
- HA model : Krusell Smith (2022), Kotlikoff, Kubler, Polbin, Scheidegger (2021)
- Spatial models : Cruz, Rossi-Hansberg (2022, 2023) among others

⇒ *Optimal and constrained policy with heterogeneous countries & trade*

## ► Unilateral vs. climate club policies :

- Climate clubs : Nordhaus (2015), Non-cooperative taxation : Chari, Kehoe (1990), Suboptimal policy : Hassler, Krusell, Olovsson (2019)
- Trade policy : Kortum, Weisbach (2023), Farrokhi, Lashkaripour (2021), Hsiao (2022), Costinot, Donalson, Vogel, Werning (2015), Adao, Costinot (2022), Antras, Fort, Gutierrez, Tintelnot (2022)

⇒ *Climate cooperation and optimal design of climate club*

## ► Optimal policy in heterogeneous agents models

- Policy with limited instruments : Diamond (1973), Davila, Walther (2022)
- Bhandari et al (2021), Le Grand, Ragot (2022), Davila, Schaab (2022) ...

⇒ *Application to climate and carbon taxation policy*

- Bhandari et al (2021), Le Grand, Ragot (2022), Davila, Schaab (2022) ...

⇒ *Application to climate and carbon taxation policy*

# Literature

## ► Nordhaus (2015)

- Examine "stable climate coalitions" (club imposing carbon tax) in a simple model
- Abstract from General Equilibrium and distributional effects
- Results : Penalty tariffs necessary to enforce a climate club

## ► Farrokhi, Lashkaripour (2021)

- Study and characterize the optimal trade policy with climate externality
- General static trade model. Results : unilateral tariffs not effective
- Sequential search for one stable climate club if EU or US join.

## ► Main contribution :

- Search for the *optimal* climate agreement
- GE on good and energy market and redistribution effects are first-order
- Cost of climate change is endogenous to policy (damages are non-linear)
- Possibility of analyzing other distributional policies (transfers, *loss and damage funds*)
- General framework for analyzing macrodynamics

## Model – Household

- ▶ Deterministic Neoclassical economy, static (for today)
  - countries  $i \in \mathbb{I}$ , heterogeneous in productivity  $z_i$ , temperature  $\tau_i$ , energy extraction cost  $C_i$
  - In each country, 3 agents :
    - (i) Household, (ii) final good firm, (iii) (fossil) energy producer

## Model – Household

- Deterministic Neoclassical economy, static (for today)
  - countries  $i \in \mathbb{I}$ , heterogeneous in productivity  $z_i$ , temperature  $\tau_i$ , energy extraction cost  $C_i$
  - In each country, 3 agents :
    - (i) Household, (ii) final good firm, (iii) (fossil) energy producer

### 1. Representative household problem in each country $i$ :

$$\mathcal{V}_i = \max_{c_{ij}} u(c_i) \quad \mathbb{P}_i c_i = w_i + \pi_i^f + t_i^{ls} \quad c_i = \left( \sum_j a_{ij}^{\frac{1}{\theta}} c_{ij}^{\frac{\theta-1}{\theta}} \right)^{\frac{\theta}{\theta-1}}$$

$$c_{ij} \quad \text{at price} \quad \overbrace{(1+t_{ij}^b)}^{\text{tariff}} \overbrace{d_{ij}}^{\text{iceberg cost}} p_j$$

$$c_i \quad \text{at price} \quad \mathbb{P}_i = \left( \sum_j a_{ij} [(1+t_{ij}^b) d_{ij} p_j]^{1-\theta} \right)^{\frac{1}{1-\theta}}$$

- Labor income  $w_i$  from final good firm (labor normalized to 1), profit  $\pi_i^f$  from fossil firm

## Model – Firms

### 2. Competitive homogeneous good producer in country $i$

$$\max_{e_i^f} p_i \mathcal{D}(\tau_i) z_i f(e_i^f) - w_i - (q^f + t_i^f) e_i^f$$

- Productivity / TFP residual  $z_i$ ,  $\Rightarrow$  creates inequalities across countries
- Fossil energy demand per unit of labor  $e_i^f$  – emitting carbon – subject to price  $q^f$  and tax/subsidy  $t^f$ .
- Climate externality on temperature  $\tau_i$ 
  - Damage affect productivity :  $\mathcal{D}(\tau) \in (0, 1]$

## Model – Energy markets & Emissions

► Competitive fossil fuels energy producer :

- Supply fossil energy  $e_i^x$  by extraction at cost  $\mathcal{C}_i^f(e_i^x)$

$$\pi_i^f = \max_{e_i^x} q^f e_i^x - \mathcal{C}_i^f(e_i^x) \mathbb{P}_i$$

- Energy traded in international markets, at price  $q^f$

$$E = \sum_{\mathbb{I}} e_i^f = \sum_{\mathbb{I}} e_i^x$$

## Model – Energy markets & Emissions

### ► Competitive fossil fuels energy producer :

- Supply fossil energy  $e_i^x$  by extraction at cost  $\mathcal{C}_i^f(e_i^x)$

$$\pi_i^f = \max_{e_i^x} q^f e_i^x - \mathcal{C}_i^f(e_i^x) \mathbb{P}_i$$

- Energy traded in international markets, at price  $q^f$

$$E = \sum_{\mathbb{I}} e_i^f = \sum_{\mathbb{I}} e_i^x$$

### ► Climate system

- Fossil energy  $e^f$  releases GHGs in the atmosphere

$$\mathcal{E} = \sum_{\mathbb{I}} e_i^f$$

- Country  $i$ 's local temperature :

$$\tau_i = \bar{\tau}_{i0} + \Delta_i \mathcal{E}$$

- Linear model + Climate sensitivity/pattern scaling factor  $\Delta_i$

## Model – Equilibrium

- Given policies  $\{t_i^f, t_{ij}^b, t_i^{ls}\}_i$ , a **competitive equilibrium** is a set of decisions  $\{c_{ij}, e_i^f, e_i^x\}_{ij}$ , states  $\{\tau_i\}_i$  and prices  $\{p_i\}_i, q^f$  such that :
  - Households choose  $\{c_{ij}\}_{ij}$  to max. utility s.t. budget constraint
  - Firm choose inputs  $\{e_i^f\}_i$  to max. profit
  - Fossil firms extract/produce  $\{e_i^x\}_i$  to max. profit.
  - Emissions  $\mathcal{E}$  affects climate  $\{\tau_i\}_i$ .
  - Government budget clear  $\sum_i t_i^{ls} = \sum_i t_i^f e_i^f + \sum_{i,j} t_{ij}^b c_{ij} d_{ij} p_j$
  - Prices  $\{p_i, q^f\}$  adjust to clear the markets for energy  $\sum_{\mathbb{I}} e_{it}^x = \sum_{\mathbb{I}} e_{it}^f$  and for each good

$$y_i := z_i \mathcal{D}(\tau_i) f(e_i^f) = \sum_{k \in \mathbb{I}} c_{ki} d_{ki} + \sum_{k \in \mathbb{I}} g_{ki}$$

with  $g_{ki}$  net export of good  $i$  to pay for energy in  $k$

In expenditure, with import shares  $s_{ij} = \frac{c_{ij} d_{ij} p_j}{c_i p_i}$ , it yields  $p_i y_i = \sum_{k \in \mathbb{I}} s_{ki} p_k y_k$

## Model – Extensions & Dynamics

- ▶ Quantitative model (today)
  - Use an energy bundle of fossil and renewable energy
  - Renewable energy input price constant (for now)
  - Use capital as well to produce at interest  $r = \rho$  (BGP)
- ▶ Dynamics, extensions :
  1. Energy market :
    - Fossil energy extraction/exploration reserves  $\Rightarrow$  Hotelling problem
  2. Households
    - Consumption / saving in bonds and in capital  $\Rightarrow$  Euler equation, Keynes-Ramsey rule
    - International markets to borrow/lend bonds
  3. Climate system with inertia : standard IAMs
  4. Population dynamics
  5. (Exogenous) growth : TFP change and Energy-augmenting Directed TC.

## Benchmark : Optimal world policy – Summary of results

- ▶ Consider a social planner maximizing world's welfare :

- Choose a single carbon tax  $\tau^f$  for the world

$$\mathcal{W} = \max_{\{\mathbf{t}, \mathbf{c}, \mathbf{e}\}_i} \sum_{i \in \mathbb{I}} \omega_i u(c_i) = \sum_{\mathbb{I}} \mathcal{W}_i$$

- ▶ Summary :

- Optimal climate policy depends on the availability of redistribution instruments (i.e. lump-sum transfers  $t_i^{ls}$  across countries)
- Without redistribution motives, optimal Pigouvian carbon tax :  $\tau^f = SCC$
- Otherwise, optimal carbon tax should account for  
(i) inequality and local climate damage, (ii) energy supply elasticities, (iii) energy terms-of-trade redistribution effects, (iv) energy demand distortions

## Benchmark : Optimal world policy – Summary of results

- ▶ Consider a social planner maximizing world's welfare :

- Choose a single carbon tax  $\tau^f$  for the world

$$\mathcal{W} = \max_{\{\mathbf{t}, \mathbf{c}, \mathbf{e}\}_i} \sum_{i \in \mathbb{I}} \omega_i u(c_i) = \sum_{\mathbb{I}} \mathcal{W}_i$$

- ▶ Summary :

- Optimal climate policy depends on the availability of redistribution instruments (i.e. lump-sum transfers  $\mathbf{t}_i^{ls}$  across countries)
  - Without redistribution motives, optimal Pigouvian carbon tax :  $\tau^f = SCC$
  - Otherwise, optimal carbon tax should account for
    - (i) inequality and local climate damage, (ii) energy supply elasticities, (iii) energy terms-of-trade redistribution effects, (iv) energy demand distortions

- ▶ Details :

- **Competitive equilibrium** Details eq 0
  - **First-Best**, with unlimited instruments Details eq 1
  - **Second-best**, Ramsey policy with limited instruments Details eq 2

## Ramsey Problem with participation constraints

- ▶ Consider that countries can “exit” climate agreement.
- ▶ **Definition** A climate agreement is a set  $\{\mathbb{J}, t^f, t^b\}$ , with  $\mathbb{J} \subseteq \mathbb{I}$  countries and a C.E.  $\{c, e, q\}$  such that :
  - Countries  $i \in \mathbb{J}$  are subject to a carbon tax  $t^f$  on fossil energy
  - Countries can leave :  
 If  $j$  exits the agreement, club members  $i \in \mathbb{J}$  pay uniform tariffs  $t_{ij}^b = t^b$  on goods from  $j$ .  
 They still trade with club members in energy at price  $q^f$ . They obtain  $\hat{c}_j$
  - Exit decision :  
 Unilateral vs. subcoalition exit, s.t. only  $\hat{\mathbb{J}}$  stay in the agreement : concept of “Core”

## Ramsey Problem with participation constraints

- ▶ Consider that countries can “exit” climate agreement.
- ▶ **Definition** A climate agreement is a set  $\{\mathbb{J}, t^f, t^b\}$ , with  $\mathbb{J} \subseteq \mathbb{I}$  countries and a C.E.  $\{c, e, q\}$  such that :
  - Countries  $i \in \mathbb{J}$  are subject to a carbon tax  $t^f$  on fossil energy
  - Countries can leave :  
If  $j$  exits the agreement, club members  $i \in \mathbb{J}$  pay uniform tariffs  $t_{ij}^b = t^b$  on goods from  $j$ . They still trade with club members in energy at price  $q^f$ . They obtain  $\hat{c}_j$
  - Exit decision :  
Unilateral vs. subcoalition exit, s.t. only  $\hat{\mathbb{J}}$  stay in the agreement : concept of “Core”
- ▶ Participation constraints :

$$u(c_i) \geq u(\hat{c}_i(\hat{\mathbb{J}})) \quad [\nu_i] \quad \forall \hat{\mathbb{J}} \subseteq \mathbb{J} \setminus \{i\}$$

## Stable climate agreements

- ▶ Consider a climate agreement  $\{\mathbb{J}, t^f, t^b\}$ 
  - It is a Nash equilibrium if it is stable to unilateral deviation,  $\hat{\mathbb{J}} = \mathbb{J} \setminus \{i\}$
  - It belongs to “core”  $\mathbb{C}(t^f, t^b)$  if it robust to deviation of sub-coalitions  $\hat{\mathbb{J}} \subseteq \mathbb{J} \setminus \{i\}$ 
    - i.e. no subcoalition would be better off than in the current agreement  $\mathbb{J}$
    - note : the “core”  $\mathbb{C}(t^f, t^b)$  can be empty
- ▶ Objective : search for the optimal climate agreement such that :

$$\max_{\mathbb{J}, t^f, t^b} \mathcal{W}(\mathbb{J}, t^f, t^b) \quad s.t. \quad \mathbb{J} \in \mathbb{C}(t^f, t^b)$$

- ▶ Welfare, for coalition  $\mathbb{J}$ , weighting all countries  $i \in \mathbb{I}$

$$\mathcal{W}(\mathbb{J}, t^f, t^b) = \sum_{i \in \mathbb{I}} \omega_i u(c_i) \quad s.t. \quad \{c, e, q\}_i \text{ is a C.E. for agreement } \{\mathbb{J}, t^f, t^b\}$$

## Approach : joint solution of policy and coalition

- Choosing policy  $\{t^f, t^b\}$  at the same time as the set of countries  $\mathbb{J}$ 
  - From one agreement  $\{\mathbb{J}, t^f, t^b\}$ , one can deduce the set  $\tilde{\mathbb{J}}$  of countries with binding participation constraints

$$\tilde{\mathbb{J}} \quad s.t. \quad u(c_i) \geq u(\hat{c}_i) \quad \forall i \in \tilde{\mathbb{J}} \quad \& \quad \forall \hat{\mathbb{J}} \subseteq \mathbb{J} \setminus \{i\}$$

- Search for the couple  $\{t^f, t^b\}$  such that  $\mathbb{J} = \tilde{\mathbb{J}}$ 
  - Difficult (but feasible)
  - Can be extended to dynamic settings :  
choose a path of  $\{t_t^f, t_t^b\}$  instead of a path of combinations of clubs
- Heuristics for an algorithm :
  - Start from the world agreement  $\{\mathbb{I}, t^{f*}, t^{b*}\}$
  - For  $\{\mathbb{J}, t^f, t^b\}$ , deduce the country with binding participation constraints  $\tilde{\mathbb{J}} = f(\mathbb{J}, t^f, t^b)$
  - Search for a fixed point  $\mathbb{J} = f(\mathbb{J}, t^f, t^b)$
- Today : Brute force solution with a small number of countries

## Leverage the combinatorial discrete choice literature

- ▶ Trade Literature on sourcing decisions :
  - Combinatorial discrete choice , c.f. Antras, Fort, Tintelnot (2017), Jia (2008), **Arkolakis, Eckert, Shi (2023)**, Alfaro-Ureña, Castro-Vincenzi, Fanelli, Morales (2024)

- ▶ Search for complementarity, given **one** policy  $\{t^f, t^b\}$

- Key concept : Single crossing difference in choice - from below (SCD-C) :

$$\Delta \mathcal{W}(\mathbb{J}', j) := \mathcal{W}(\mathbb{J}' \cup j) - \mathcal{W}(\mathbb{J}') > \Delta \mathcal{W}(\mathbb{J}, j) \quad \text{when } \mathbb{J}' \supseteq \mathbb{J} \quad \text{for all } j \in \mathbb{I}$$

- Adding an extra member  $j$  is increasingly profitable with the size of the club  $\mathbb{J}$
  - Can use a “squeezing procedure” to bypass the combinatorial problem

- ▶ Search optimal combination for **all** policies  $\{t^f, t^b\}$  ?

- Single crossing difference in type (SCD-T) :

$$\text{Define } \Lambda_i(\mathbb{J}) = \{t^f, t^b \in \mathbb{R}_+^2 \mid \Delta \mathcal{W}(\mathbb{J}, i) > 0\}$$

- Welfare function has SCD-T if  $\Lambda_i(\mathbb{J})$  is a connected set

# Quantification

- ▶ Quadratic damage as in Nordhaus DICE  $y = \mathcal{D}_i(\tau)\bar{y}$  with  $\mathcal{D}_i(\tau) = e^{-\gamma_i(\tau-\tau_{i0})^2}$
- ▶ Energy parameters to match production/reserves,  
Isoelastic cost function  $\mathcal{C}_i(e_i^x) = \bar{\nu}_i(e_i^x/\mathcal{R}_i)^{1+\nu}\mathcal{R}_i$
- ▶ Armington model, distance  $d_{ij}$  and preferences  $a_{ij}$  to match import shares  $s_{ij} = \frac{c_{ij}d_{ij}p_j}{c_i p_i}$
- ▶ Production  $\bar{y} = zf(\ell_i, k_i, e_i^f, e_i^r)$ 
  - Nested CES energy vs. labor-capital Cobb-Douglas bundle  $k_i^\alpha \ell_i^{1-\alpha}$  (elasticity  $\sigma_y < 1$ ), and fossil/renewable  $\sigma_e > 1$ ,  $CES(e_i^f, e_i^r)$
  - TFP, and DTC,  $z_i, z_i^e$ , calibrated to match GDP / energy shares data.
- ▶ Details [More details](#)

## Welfare and Pareto weights

- Recall welfare :

$$\mathcal{W}(\mathbb{J}) = \sum_{i \in \mathbb{I}} \omega_i u(c_i)$$

- Choose Pareto weights  $\omega_i$  per country such that :

$$\omega_i = \frac{1}{u'(c_i)}$$

for  $c_i$  consumption in initial equilibrium “without climate change“, i.e. year = 2000

- Imply that there is no redistribution motive (in  $t = 2000$ )

$$\omega_i u'(c_i) = \omega_j u'(c_j) \quad \forall i, j \in \mathbb{I}$$

- Climate change, carbon taxation and climate agreement (tax and tariffs) have redistributive effects  $\Rightarrow$  will change distribution of  $c_i$ .

## Numerical Application - Sample of “10 regions”

Thomas Bourany (UChicago)

- Data on trade shares  $s_{ij} = \frac{c_{ij}d_{ij}p_j}{c_i p_i}$ , 10 regions, Average 2000-2015

Optimal Design of Climate Agreements

March 2024

18 / 26

# Cost of Climate Change

Welfare loss, Climate change, 2050 vs. 2000

► Trade reallocation, change in shares  $s_{ij}$  due to climate change

## Gains from trade

- ▶ Static problem : Calibration subject to changes
- ▶ Losses from increasing trade tariffs :
- ▶ Losses from autarky

Picture of gains from trade per country here

## Gains from cooperation – Second Best

- ▶ Static problem : Calibration subject to changes
- ▶ Optimal carbon tax, Second Best :  $\sim \$215/tC$  ( $\sim \$880/tCO_2$ )
- ▶ Reduce fossil fuels /  $CO_2$  emissions by 24% compared to Business as Usual (BAU)
- ▶ Welfare difference between World Second-Best Policy and BAU (Comp. Eq.)

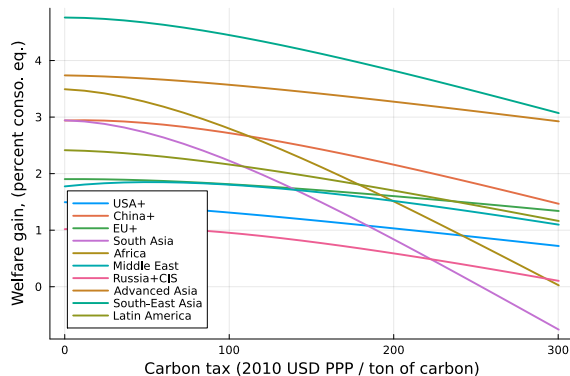

## Gains from cooperation – Second Best – Tax variation

## Free riding problem ... solved with trade tariffs

- Welfare difference between World Second-Best Policy and Unilateral deviation
  - Recover Nordhaus (2015) result

## Taxes combination can recover any climate coalition

- ▶ Choice of any couples  $(t^f, t^b) \in \mathbb{R}_+^2$  allow to enforce any coalitions (any number of countries)
  - ▶ Trade penalties change the country's outside options, ruling out unilateral deviations
- ⇒ One can reproduce the second-best : full-cooperation, high-tax and maximum welfare

## Nash equilibrium : conclusion – Optimal agreement is the Second-Best

- ▶ With flexible  $t^f, t^b$ , the "agreement designer" can reproduce the world's optimal policy
  - Carbon taxation corrects externality, accounting for terms-of-trade / redistribution effects
  - Trade tariffs serve as penalties to enforce the stability of the club

## Nash equilibrium : conclusion – Optimal agreement is the Second-Best

- ▶ With flexible  $t^f$ ,  $t^b$ , the "agreement designer" can reproduce the world's optimal policy
  - Carbon taxation corrects externality, accounting for terms-of-trade / redistribution effects
  - Trade tariffs serve as penalties to enforce the stability of the club
- ▶ Same mechanisms with conditional transfers (loss and damages funds – COP27)
  - Ensure stability (change one side of the participation constraint)
  - How to decide/rationalize who "deserves" the funds ? the poorest ? the most vulnerable ? or the countries with the highest outside options ?
  - Coase type of arguments : harder to bargain on  $I$ -instruments (c.f. Weitzman 2014)
- ▶ Obvious conclusion ?
  - With enough instruments, easy to reach full coordination
  - In practice, coordination failure to implement binding agreements

## Conclusion

- ▶ In this project, I solve for the optimal climate policy
  - Accounting for inequality as it depends on the availability of transfer mechanisms
  - Redistributing through GE effects on energy and good markets  $\Rightarrow$  terms-of-trade effects
  
- ▶ Climate agreement design jointly solves for :
  - The optimal choice of countries participating
  - The carbon tax level, both for correcting externality & respecting participation constraints
  
- ▶ Can reproduce any coalition with arbitrary trade tariffs or conditional transfers
  - Can achieve the second-best, world climate agreement and largest emission reductions
  - Objective to extend this to dynamic settings where the tradeoffs are less obvious/more realistic.

# Appendices

## Step 0 : Competitive equilibrium & Trade

- ▶ Each household in country  $i$  maximize utility and firms maximize profit
- ▶ Standard trade model results :
  - Consumption and trade :

$$s_{ij} = \frac{c_{ij}p_{ij}}{c_i \mathbb{P}_i} = a_{ij} \frac{(d_{ij}(1+t_{ij}^b)p_j)^{1-\theta}}{\sum_k a_{ik}(d_{ik}(1+t_{ik}^b)p_k)^{1-\theta}} \quad \& \quad \mathbb{P}_i = \left( \sum_j a_{ij}(d_{ij}p_j)^{1-\theta} \right)^{\frac{1}{1-\theta}}$$

- Energy consumption doesn't internalize climate damage :

$$p_i MPE_i = q^e$$

- Inequality, as measured in local welfare units :

$$\lambda_i = u'(c_i)$$

- “Local Social Cost of Carbon”, for region  $i$

$$LCC_i = \frac{\partial \mathcal{W}_i / \partial \mathcal{E}}{\partial \mathcal{W}_i / \partial w_i} = \frac{\psi_i^{\mathcal{E}}}{\lambda_i} = -\Delta_i \mathcal{D}'(\tau_i) z_{if}(e_i^f) \frac{p_i}{\mathbb{P}_i} \quad (> 0 \text{ if heat causes losses})$$

## Step 1 : World First-best policy

- Maximizing welfare of the world Social Planner :

$$\mathcal{W} = \max_{\{\mathbf{t}, \mathbf{e}, \mathbf{q}\}_i} \sum_{i \in \mathbb{I}} \omega_i u(c_i) = \sum_{\mathbb{I}} \mathcal{W}_i$$

- Full array of instruments : cross-countries lump-sum transfers  $\mathbf{t}_i^{ls}$ , individual carbon taxes  $\mathbf{t}_i^f$  on energy  $e_i^f$ , bilateral tariffs  $\mathbf{t}_{ij}^b$
  - Budget constraint :  $\sum_i \mathbf{t}_i^{ls} = \sum_i \mathbf{t}_i^f e_i^f + \sum_{i,j} \mathbf{t}_{ij}^b c_{ij} d_{ij} p_j$
- Maximize welfare subject to
- Market clearing for good  $[\mu_i]$ , market clearing for energy  $\mu^e$

back

## Step 1 : World First-best policy

► Social planner results :

- Consumption :

$$\omega_i u'(c_i) = \left[ \sum_j a_{ij} (d_{ij} \omega_j \mu_j)^{1-\theta} \right]^{\frac{1}{1-\theta}}$$

- Energy use :

$$\omega_i \mu_i MPe_i = \mu^e + SCC$$

- Social cost of carbon :

$$SCC = - \frac{\sum_j \Delta_j \omega_j \mu_j \mathcal{D}'_j(\tau_j) \bar{y}_j}{\frac{1}{I} \sum_j \omega_j \mu_j}$$

back

## Step 2 : World optimal Ramsey policy

- Maximizing welfare of the world Social Planner :

$$\mathcal{W} = \max_{\{\mathbf{t}, \mathbf{e}, \mathbf{q}\}_i} \sum_{i \in \mathbb{I}} \omega_i u(c_i) = \sum_{\mathbb{I}} \mathcal{W}_i$$

- One single instrument : uniform carbon tax  $\tau^f$  on energy  $e_i^f$
  - Rebate tax lump-sum to HHs  $t_i^{ls} = \tau^f e_i^f$
- Ramsey policy : Primal approach, maximize welfare subject to
- Budget constraint  $[\lambda_i]$ , Market clearing for good  $[\mu_i]$ , market clearing for energy
  - Optimality (FOC) conditions for good demands  $[\eta_{ij}]$ , energy demand & supply, etc.
  - Trade-off faced by the planner :
    - (i) Correcting externality, (ii) Redistributive effect, (iii) Distort energy demand and supply

back

## Step 2 : World optimal Ramsey policy

- The planner takes into account

- (i) the marginal value of wealth  $\lambda_i$
- (ii) the shadow value of good  $i$ , from market clearing,  $\mu_i$  :

$$\text{w/o trade} \quad \omega_i u'(c_i) = \omega_i \lambda_i$$

$$\text{vs. w/ trade in goods :} \quad \omega_i u'(c_i) = \left( \sum_{j \in \mathbb{I}} a_{ij} (d_{ij} p_j)^{1-\theta} \left[ \omega_i \lambda_i + \omega_j \mu_j + \eta_{ij} (1 - s_{ij}) \right] \right)^{\frac{1}{1-\theta}}$$

- Relative welfare weights, representing inequality

$$\text{w/o trade :} \quad \hat{\lambda}_i = \frac{\omega_i \lambda_i}{\bar{\lambda}} = \frac{\omega_i u'(c_i)}{\frac{1}{I} \sum_{\mathbb{I}} \omega_j u'(c_j)} \leq 1 \quad \Rightarrow \quad \text{ceteris paribus, poorer countries have higher } \hat{\lambda}_i$$

$$\text{vs. w/ trade :} \quad \hat{\lambda}_i = \frac{\omega_i (\lambda_i + \mu_i)}{\frac{1}{I} \sum_{\mathbb{I}} \omega_i (\lambda_i + \mu_i)} \leq 1$$

## Step 2 : Optimal policy – Social Cost of Carbon

► Key objects : Local vs. Global Social Cost of Carbon :

- Marginal cost of carbon  $\psi_i^{\mathcal{E}}$  for country  $i$
- “Local social cost of carbon” (LCC) for region  $i$  :

$$LCC_i := \frac{\partial \mathcal{W}_i / \partial \mathcal{E}}{\partial \mathcal{W}_i / \partial w_i} = \frac{\psi_i^{\mathcal{E}}}{\lambda_i} = -\Delta_i \mathcal{D}'(\tau_i) z_{if}(e_i^f) p_i \quad (> 0 \text{ if heat causes losses})$$

## Step 2 : Optimal policy – Social Cost of Carbon

### ► Key objects : Local vs. Global Social Cost of Carbon :

- Marginal cost of carbon  $\psi_i^{\mathcal{E}}$  for country  $i$
- “Local social cost of carbon” (LCC) for region  $i$  :

$$LCC_i := \frac{\partial \mathcal{W}_i / \partial \mathcal{E}}{\partial \mathcal{W}_i / \partial w_i} = \frac{\psi_i^{\mathcal{E}}}{\lambda_i} = -\Delta_i \mathcal{D}'(\tau_i) z_{if}(e_i^f) p_i \quad (> 0 \text{ if heat causes losses})$$

- Social Cost of Carbon for the planner :

$$SCC := \frac{\partial \mathcal{W} / \partial \mathcal{E}}{\partial \mathcal{W} / \partial w} = \frac{\sum_{\mathbb{I}} \omega_i \psi_i^{\mathcal{E}}}{\frac{1}{I} \sum_{\mathbb{I}} \omega_i (\lambda_i + \mu_i)}$$

- Social Cost of Carbon integrates these inequalities :

$$SCC = \sum_{\mathbb{I}} \hat{\lambda}_i LCC_i = \sum_{\mathbb{I}} LCC_i + \mathbb{Cov}_i(\hat{\lambda}_i, LCC_i)$$

## Step 2 : Optimal policy – Other motives

- ▶ Taxing fossil energy has additional redistributive effects :
  1. Through energy markets : distort supply, lowers eq. fossil price, benefit net importers
  2. Distort energy demand, of countries that need more or less energy
- ▶ New measure : Social Value of Fossil (SVF)

$$SVF := \frac{\partial \mathcal{W} / \partial E}{\partial \mathcal{W} / \partial w} = c_{EE}^f \text{Cov}_i \left( \hat{\lambda}_i, e_i^f - e_i^x \right) - \text{Cov}_i \left( \hat{\lambda}_i, \frac{q^f (1 - s_i^f)}{\sigma} \right)$$

- Params :  $c_{EE}^f$  agg. fossil supply elasticity,  $s_i^f$  energy cost share and  $\sigma$  energy demand elasticity

## Step 2 : Optimal policy – Other motives

- ▶ Taxing fossil energy has additional redistributive effects :
  1. Through energy markets : distort supply, lowers eq. fossil price, benefit net importers
  2. Distort energy demand, of countries that need more or less energy
- ▶ New measure : Social Value of Fossil (SVF)

$$SVF := \frac{\partial \mathcal{W} / \partial E}{\partial \mathcal{W} / \partial w} = \underbrace{C_{EE}^f}_{\text{agg. supply distortion}} \underbrace{\text{Cov}_i(\hat{\lambda}_i, e_i^f - e_i^x)}_{\text{terms-of-trade redistribution}} - \underbrace{\text{Cov}_i\left(\hat{\lambda}_i, \frac{q^f(1-s_i^f)}{\sigma}\right)}_{\text{demand distortion}}$$

- Params :  $C_{EE}^f$  agg. fossil supply elasticity,  $s_i^f$  energy cost share and  $\sigma$  energy demand elasticity

## Step 2 : Optimal policy – Other motives

- ▶ Taxing fossil energy has additional redistributive effects :
  1. Through energy markets : distort supply, lowers eq. fossil price, benefit net importers
  2. Distort energy demand, of countries that need more or less energy
- ▶ New measure : Social Value of Fossil (SVF)

$$SVF := \frac{\partial \mathcal{W} / \partial E}{\partial \mathcal{W} / \partial w} = c_{EE}^f \text{Cov}_i \left( \hat{\lambda}_i, e_i^f - e_i^x \right) - \text{Cov}_i \left( \hat{\lambda}_i, \frac{q^f (1 - s_i^f)}{\sigma} \right)$$

- Params :  $c_{EE}^f$  agg. fossil supply elasticity,  $s_i^f$  energy cost share and  $\sigma$  energy demand elasticity
- ▶ Proposition 2 : Optimal fossil energy tax :

$$\Rightarrow \quad t^f = SCC + SVF$$

– Social cost of carbon :  $SCC = \sum_{\mathbb{I}} \hat{\lambda}_i LCC_i$

## Step 3 : Ramsey Problem with participation constraints

- ▶ Consider that countries can “exit” climate agreement.
- ▶ For a climate “club” of  $\mathbb{J} \subset \mathbb{I}$  countries :
  - Countries  $i \in \mathbb{J}$  are subject to a carbon tax  $t^f$
  - Countries  $i \in \mathbb{J}$  can unilaterally leave, subject to retaliation tariff  $t^{b,r}$  on goods and get consumption  $\tilde{c}_i$
  - Countries  $i \notin \mathbb{J}$  trade in goods subject to tariff  $t^b$  with club members and countries outside the club. They still trade with the club members in energy at price  $q^f$

## Step 3 : Ramsey Problem with participation constraints

- ▶ Consider that countries can “exit” climate agreement.
- ▶ For a climate “club” of  $\mathbb{J} \subset \mathbb{I}$  countries :
  - Countries  $i \in \mathbb{J}$  are subject to a carbon tax  $t^f$
  - Countries  $i \in \mathbb{J}$  can unilaterally leave, subject to retaliation tariff  $t^{b,r}$  on goods and get consumption  $\tilde{c}_i$
  - Countries  $i \notin \mathbb{J}$  trade in goods subject to tariff  $t^b$  with club members and countries outside the club. They still trade with the club members in energy at price  $q^f$
- ▶ Participation constraints :

$$u(c_i) \geq u(\tilde{c}_i) \quad [\nu_i]$$

- ▶ Welfare :

$$\mathcal{W} = \max_{\{t, e, q\}_i} \sum_{\mathbb{J}} \omega_i u(c_i) + \sum_{\mathbb{J}^c} \alpha \omega_i u(c_i)$$

## Step 3 : Ramsey Problem with participation constraints

### ► Participation constraints

$$u(c_i) \geq u(\tilde{c}_i) \quad [\nu_i]$$

### ► Proposition 3.1 : Second-Best social valuation with participation constraints

- Participation incentives change our measure of inequality

$$\text{w/ trade :} \quad \omega_i(1+\nu_i)u'(c_i) = \left( \sum_{j \in \mathbb{I}} a_{ij}(d_{ij}p_j)^{1-\theta} \left[ \omega_i \tilde{\lambda}_i + \omega_j \tilde{\mu}_j + \tilde{\eta}_{ij}(1-s_{ij}) \right] \right)^{\frac{1}{1-\theta}}$$

$$\Rightarrow \quad \hat{\tilde{\lambda}}_i = \frac{\omega_i(\tilde{\lambda}_i + \tilde{\mu}_i)}{\frac{1}{J} \sum_{j \in \mathbb{J}} \omega_j(\tilde{\lambda}_i + \tilde{\mu}_i)} \neq \hat{\lambda}_i$$

$$\text{vs. w/o trade} \quad \hat{\tilde{\lambda}}_i = \frac{\omega_i(1+\nu_i)u'(c_i)}{\frac{1}{J} \sum_{j \in \mathbb{J}} \omega_j(1+\nu_j)u'(c_j)} \neq \hat{\lambda}_i$$

- Similarly, the “effective Pareto weights” are  $\alpha\omega_i$  for countries outside the club  $i \notin \mathbb{J}$  and  $\omega_i(\alpha - \nu_i)$  for retaliation policy on  $i \in \mathbb{J}$

## Step 3 : Participation constraints & Optimal policy

### ► Proposition 3.2 : Second-Best taxes :

- Taxation with imperfect instruments :
  - Climate change & general equilibrium effects on fossil market affects all countries  $i \in \mathbb{I}$
  - Need to adjust for the "outside" countries  $i \notin \mathbb{J}$  not subject to the tax, which weight on the energy market as  $\vartheta_{\mathbb{J}^c} \approx \frac{E_{\mathbb{J}^c}}{E_{\mathbb{I}}} \frac{\nu \sigma}{q^f (1-s^f)}$   
with  $\nu$  fossil supply elasticity,  $\sigma$  energy demand elasticity and  $s^f$  energy cost share.
- Optimal fossil energy tax  $t^f(\mathbb{J})$  :

$$\begin{aligned} \Rightarrow \quad t^f(\mathbb{J}) &= \text{SCC} + \text{SVF} \\ &= \frac{1}{1 - \vartheta_{\mathbb{J}^c}} \sum_{i \in \mathbb{I}} \tilde{\lambda}_i \text{LCC}_i + \frac{1}{1 - \vartheta_{\mathbb{J}^c}} C_{EE}^f \sum_{i \in \mathbb{I}} \tilde{\lambda}_i (e_i^f - e_i^x) - \sum_{i \in \mathbb{J}} \tilde{\lambda}_i \frac{q^f (1-s_i^f)}{\sigma} \end{aligned}$$

- Optimal tariffs/export taxes  $t^{b,r}(\mathbb{J})$  and  $t^b(\mathbb{J})$  : In search for a closed-form expression  
As of now, only opaque system of equations (fixed point w/ demand/multipliers)

## Countries' incentives – Model w/o trade in goods

- ▶ Experiment : Model with trade in energy but not in “goods”
  - Start from the equilibrium where carbon tax  $t^f(\mathbb{J}) = 0$ ,  
     $\Rightarrow$  country  $i$  is indifferent to join the club  $\mathbb{J}$  or not
  - Linear approximation around that point  $\Rightarrow$  small changes in carbon tax  $dt^f$

## Countries' incentives – Model w/o trade in goods

- Experiment : Model with trade in energy but not in “goods”
  - Start from the equilibrium where carbon tax  $t^f(\mathbb{J}) = 0$ ,  
 $\Rightarrow$  country  $i$  is indifferent to join the club  $\mathbb{J}$  or not
  - Linear approximation around that point  $\Rightarrow$  small changes in carbon tax  $dt^f$
  - Change in welfare if  $i \in \mathbb{J}$  vs.  $i \notin \mathbb{J}$

$$\begin{aligned} \frac{d\mathcal{W}_{i|i \in \mathbb{J}}}{u'(c_i^{i \in \mathbb{J}})} - \frac{d\mathcal{W}_{i|i \notin \mathbb{J}}}{u'(c_i^{i \notin \mathbb{J}})} = & -e_i dt^f - \gamma_i (\tau_i - \tau_{i0})^\delta y_i \Delta_i (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & - e_i \frac{q^f \nu}{E_{\mathbb{I}}} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) + \pi_i \frac{(1+\nu)}{E} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \end{aligned}$$

- Difference in the GE effect on energy markets, for  $\sigma \approx 1$

$$dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}} = - \left( E_{\mathbb{J}} - E_{\mathbb{J} \setminus \{i\}} \right) \frac{\sigma dt^f}{q^f (1 - s^f)} \frac{1}{1 + \frac{\nu \sigma}{(1 - s^f)}}$$

- Params :  $\sigma$  energy demand elast<sup>y</sup>,  $s^f$  energy cost share,  $\nu$  energy supply elas<sup>y</sup>, Climate damage  $\gamma_i$  and curv.  $\delta$

## Countries' incentives – Model w/o trade in goods

- Experiment : Model with trade in energy but not in “goods”
  - Start from the equilibrium where carbon tax  $t^f(\mathbb{J}) = 0$ ,  
 $\Rightarrow$  country  $i$  is indifferent to join the club  $\mathbb{J}$  or not
  - Linear approximation around that point  $\Rightarrow$  small changes in carbon tax  $dt^f$
  - Change in welfare if  $i \in \mathbb{J}$  vs.  $i \notin \mathbb{J}$

$$\begin{aligned} \frac{d\mathcal{W}_{i|i \in \mathbb{J}}}{u'(c_i^{i \in \mathbb{J}})} - \frac{d\mathcal{W}_{i|i \notin \mathbb{J}}}{u'(c_i^{i \notin \mathbb{J}})} = & -e_i dt^f - \gamma_i (\tau_i - \tau_{i0})^\delta y_i \Delta_i (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & - e_i \frac{q^f \nu}{E_I} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) + \pi_i \frac{(1+\nu)}{E} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \end{aligned}$$

- Difference in the GE effect on energy markets, for  $\sigma \approx 1$

$$dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}} = - \left( E_{\mathbb{J}} - E_{\mathbb{J} \setminus \{i\}} \right) \frac{\sigma dt^f}{q^f (1 - s^f)} \frac{1}{1 + \frac{\nu \sigma}{(1 - s^f)}}$$

- Params :  $\sigma$  energy demand elast<sup>y</sup>,  $s^f$  energy cost share,  $\nu$  energy supply elas<sup>y</sup>, Climate damage  $\gamma_i$  and curv.  $\delta$

## Countries' incentives – Armington Model with trade in goods

- Trade in energy and goods *à la* Armington, Linear approx. around  $t^f \approx 0$  and  $t^b \approx 0$ 
  - Change in welfare if  $i \in \mathbb{J}$ , vs.  $i \notin \mathbb{J}$

$$\begin{aligned} \frac{d\mathcal{W}_{i|i \in \mathbb{J}}}{u'(c_i^{i \in \mathbb{J}})c_i} - \frac{d\mathcal{W}_{i|i \notin \mathbb{J}}}{u'(c_i^{i \notin \mathbb{J}})c_i} = & -e_i dt^f - \gamma_i(\tau_i - \tau_{i0})^\delta \eta_i^y \Delta_i (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & - e_i \frac{q^f \nu}{E_{\mathbb{I}}} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) + \eta_i^f \frac{(1+\nu)}{E} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & + \eta_i^y \left( \frac{dp_i}{p_i} \Big|_{i \in \mathbb{J}} - \frac{dp_i}{p_i} \Big|_{i \notin \mathbb{J}} \right) - s_{i\mathbb{J}^c} dt^b - \sum_{j \in \mathbb{I}} s_{ij} \left( \frac{dp_j}{p_j} \Big|_{i \in \mathbb{J}} - \frac{dp_j}{p_j} \Big|_{i \notin \mathbb{J}} \right) \end{aligned}$$

## Countries' incentives – Armington Model with trade in goods

- Trade in energy and goods *à la* Armington, Linear approx. around  $t^f \approx 0$  and  $t^b \approx 0$

- Change in welfare if  $i \in \mathbb{J}$ , vs.  $i \notin \mathbb{J}$

$$\begin{aligned} \frac{d\mathcal{W}_{i|i \in \mathbb{J}}}{u'(c_i^{i \in \mathbb{J}})c_i} - \frac{d\mathcal{W}_{i|i \notin \mathbb{J}}}{u'(c_i^{i \notin \mathbb{J}})c_i} = & -e_i dt^f - \gamma_i(\tau_i - \tau_{i0})^\delta \eta_i^y \Delta_i (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & - e_i \frac{q^f \nu}{E_{\mathbb{I}}} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) + \eta_i^f \frac{(1+\nu)}{E} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & + \eta_i^y \left( \frac{dp_i}{p_i} \Big|_{i \in \mathbb{J}} - \frac{dp_i}{p_i} \Big|_{i \notin \mathbb{J}} \right) - s_{i\mathbb{J}^c} dt^b - \sum_{j \in \mathbb{I}} s_{ij} \left( \frac{dp_j}{p_j} \Big|_{i \in \mathbb{J}} - \frac{dp_j}{p_j} \Big|_{i \notin \mathbb{J}} \right) \end{aligned}$$

- GE effect on energy markets, same as before
- GE effect on goods markets, equilibrium on expenditure  $v_i = p_i c_i$ , for  $\theta \approx 1$

$$\frac{dv_i}{v_i} = \sum_{k \in \mathbb{I}} \mathcal{P}_k \alpha_{ki} \left( \frac{dv_k}{v_k} - \theta \frac{dt_{ki}^b}{1+t_{ki}^b} \right) \quad \alpha_{ki} = \frac{c_{ki} d_{ki} p_i}{\sum_{\ell} c_{k\ell} d_{k\ell} p_{\ell}} \frac{v_k}{v_i} = s_{ki} \frac{v_k}{(1+t_{ki}^b) v_i}$$

- Params :  $\sigma$  energy demand elasticity,  $s^f$  energy cost share,  $\nu$  energy supply elasticity, share of output  $y$  in income  $\eta_i^y = \frac{y_i p_i}{v_i}$ , fossil rent share  $\eta_i^f = \frac{\pi_i}{v_i}$

## Countries' incentives – Armington Model with trade in goods

- Trade in energy and goods *à la* Armington, Linear approx. around  $t^f \approx 0$  and  $t^b \approx 0$

- Change in welfare if  $i \in \mathbb{J}$ , vs.  $i \notin \mathbb{J}$

$$\begin{aligned} \frac{d\mathcal{W}_{i|i \in \mathbb{J}}}{u'(c_i^{i \in \mathbb{J}})c_i} - \frac{d\mathcal{W}_{i|i \notin \mathbb{J}}}{u'(c_i^{i \notin \mathbb{J}})c_i} = & -e_i dt^f - \gamma_i(\tau_i - \tau_{i0})^\delta \eta_i^y \Delta_i (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & - e_i \frac{q^f \nu}{E_{\mathbb{I}}} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) + \eta_i^f \frac{(1+\nu)}{E} (dE_{i \in \mathbb{J}} - dE_{i \notin \mathbb{J}}) \\ & + \eta_i^y \left( \frac{dp_i}{p_i} \Big|_{i \in \mathbb{J}} - \frac{dp_i}{p_i} \Big|_{i \notin \mathbb{J}} \right) - s_{i\mathbb{J}^c} dt^b - \sum_{j \in \mathbb{I}} s_{ij} \left( \frac{dp_j}{p_j} \Big|_{i \in \mathbb{J}} - \frac{dp_j}{p_j} \Big|_{i \notin \mathbb{J}} \right) \end{aligned}$$

- GE effect on energy markets, same as before
- GE effect on goods markets, equilibrium on expenditure  $v_i = \mathbb{P}_i c_i$ , for  $\theta \approx 1$

$$\frac{dv_i}{v_i} = \sum_{k \in \mathbb{I}} \mathcal{P}_k \alpha_{ki} \left( \frac{dv_k}{v_k} - \theta \frac{dt_{ki}^b}{1+t_{ki}^b} \right) \quad \alpha_{ki} = \frac{c_{ki} d_{ki} p_i}{\sum_{\ell} c_{k\ell} d_{k\ell} p_{\ell}} \frac{v_k}{v_i} = s_{ki} \frac{v_k}{(1+t_{ki}^b) v_i}$$

- Params :  $\sigma$  energy demand elasticity,  $s^f$  energy cost share,  $\nu$  energy supply elasticity, share of output  $y$  in income  $\eta_i^y = \frac{y_i p_i}{v_i}$ , fossil rent share  $\eta_i^f = \frac{\pi_i}{v_i}$

## Complementarity in coalition formation – Model w/o trade in goods

- Is marginal gain  $\Delta\mathcal{W}(\mathbb{J}, j) := \mathcal{W}(\mathbb{J} \cup j) - \mathcal{W}(\mathbb{J})$  “growing” in  $\mathbb{J}$ ?
- Linear approximation for small  $\{t^f, t^b\}$

$$\begin{aligned} \Delta\mathcal{W}(\mathbb{J}, j) = & -\omega_j u'(c_j) e_j dt^f + \left[ \sum_{i \in \mathbb{I}} \omega_i u'(c_i) \Delta_i \gamma_i (\tau_i - \tau_{i0})^\delta y_i \right] \frac{\sigma e_j dt^f}{q^f (1 - s^f + \nu \sigma)} \\ & + \left[ \sum_{i \in \mathbb{I}} \omega_i u'(c_i) e_i \right] \frac{1}{1 + \frac{1-s^f}{\nu \sigma}} \frac{e_j dt^f}{E_{\mathbb{I}}} - \left[ \sum_{i \in \mathbb{I}} \omega_i u'(c_i) \pi_i \right] \frac{(1+\nu)}{E_{\mathbb{I}}} \frac{\sigma e_j dt^f}{q^f (1 - s^f + \nu \sigma)} \end{aligned}$$

- Free-riding problem :  $\Delta\mathcal{W}(\mathbb{J}, j)$  could be negative
- If  $\Delta\mathcal{W}(\mathbb{J}, j) > 0$ , what effects does  $\mathbb{J}$  have on marginal gain ?
  - Marginal climate benefit decreases in  $\mathbb{J}$ , since temperature  $\tau_i$  declines !
  - G.E. effect on energy price :  $E_{\mathbb{I}}$ ,  $q$  and  $\pi^f$  decreases with  $\mathbb{J}$ , effect on demand ambiguous
  - Similar formula for the case with trade tariffs : Work in progress.

## Quantification – Firms

- Production function  $y_i = \mathcal{D}_i^y(\tau_i) z_i f(k, \varepsilon(e^f, e^r))$

$$f_i(k, \ell, \varepsilon(e^f, e^r)) = \left[ (1 - \epsilon_i)^{\frac{1}{\sigma_y}} (k^\alpha \ell^{1-\alpha})^{\frac{\sigma_y-1}{\sigma_y}} + \epsilon_i^{\frac{1}{\sigma_y}} (z_i^e \varepsilon_i(e^f, e^r))^{\frac{\sigma_y-1}{\sigma_y}} \right]^{\frac{\sigma_y}{\sigma_y-1}}$$

$$\varepsilon(e^f, e^r) = \left[ \omega_i^{\frac{1}{\sigma_e}} (e^f)^{\frac{\sigma_e-1}{\sigma_e}} + (1 - \omega_i)^{\frac{1}{\sigma_e}} (e^r)^{\frac{\sigma_e-1}{\sigma_e}} \right]^{\frac{\sigma_e}{\sigma_e-1}}$$

- Calibrate TFP  $z_i$  to match  $y_i = GDP_i$  per capita in 2011 (PPP).
- Today :  $\omega_i = \bar{\omega} = 85\%$  and  $\epsilon_i = \bar{\epsilon} = 12\%$  for all  $i$
- Future :  $(z_i^e, \omega_i, \epsilon_i)$  to match Energy/GDP  $(e_i^f + e_i^r)/y_i$  and energy mix  $(e_i^f, e_i^r)$

- Damage functions in production function  $y$  :

$$\mathcal{D}_i^y(\tau) = e^{-\gamma_i^{\pm,y}(\tau - \tau_i^*)^2}$$

- Asymmetry in damage to match empirics with  $\gamma^y = \gamma^{+,y} \mathbb{1}_{\{\tau > \tau_i^*\}} + \gamma^{-,y} \mathbb{1}_{\{\tau < \tau_i^*\}}$
- Today  $\gamma_i^{\pm,y} = \bar{\gamma}^{\pm,y}$  &  $\tau_i^* = \bar{\alpha} \tau_{it0} + (1 - \bar{\alpha}) \tau^*$

## Quantification – Energy markets

- ▶ Fossil production  $e_{it}^x$  and reserve  $\mathcal{R}_{it}$ 
  - Cost  $\mathcal{C}_i(e^x, \mathcal{R}) = \frac{\bar{\nu}_i}{1+\nu_i} \left(\frac{e^x}{\mathcal{R}}\right)^{1+\nu_i} \mathcal{R}$
  - Now :  $\bar{\nu}_i$  to match extraction data  $e_i^x$ ,  $\mathcal{R}_{it}$  calibrated to *proven reserves* data from BP.  
 $\nu_i = \nu = 1$  quadratic extraction cost.
  - Future : Choose  $(\bar{\nu}_i, \nu_i, \mathcal{R}_i)$  to match marginal cost  $\mathcal{C}_e$  & extraction data  $e_i^x$  (BP, IEA)

## Quantification – Energy markets

- ▶ Fossil production  $e_{it}^x$  and reserve  $\mathcal{R}_{it}$ 
  - Cost  $\mathcal{C}_i(e^x, \mathcal{R}) = \frac{\bar{\nu}_i}{1+\nu_i} \left( \frac{e^x}{\mathcal{R}} \right)^{1+\nu_i} \mathcal{R}$
  - Now :  $\bar{\nu}_i$  to match extraction data  $e_i^x$ ,  $\mathcal{R}_{it}$  calibrated to *proven reserves* data from BP.  
 $\nu_i = \nu = 1$  quadratic extraction cost.
  - Future : Choose  $(\bar{\nu}_i, \nu_i, \mathcal{R}_i)$  to match marginal cost  $\mathcal{C}_e$  & extraction data  $e_i^x$  (BP, IEA)
  
- ▶ Renewable : Production  $\bar{e}_{it}^r$  and price  $q_{it}^r$ 
  - Now :  $q_{it}^r = z^r e^{-g_r t}$ , with  $g_r$  growth rate in renewable energy price decreases.
  - Future : Choose  $z_i^r$  to match the energy mix  $(e_i^f, e_i^r)$

[back](#)

## Quantification – Future Extensions :

### ► Damage parameters :

- $\gamma_i^{\pm,y}$  depends on daily temperature distribution  $\tau \sim \mathcal{T}_i(\bar{T}, \sigma^T)$  following Rudik et al. (2022)
- Use Climate Lab's (Greenstone et al) estimates for damage  $\gamma_i$  ?

### ► Fossil Energy markets :

- Divide fossils  $e_{it}^f / e_{it}^x$  into oil/gas/coal
- Match the production/cost/reserves data across countries
- Use a dynamic model : extraction/exploration a la Hotelling

### ► Renewables Energy markets :

- Make the problem dynamic with investment in capacity  $C_{it}^r$

### ► Population dynamics

- Match UN forecast for growth rate / fertility

# Calibration

TABLE – Baseline calibration (★ = subject to future changes)

<i>Technology &amp; Energy markets</i>			
$\alpha$	0.35	Capital share in $f(\cdot)$	Capital/Output ratio
$\epsilon$	0.12	Energy share in $f(\cdot)$	Energy cost share (8.5%)
$\sigma$	0.3	Elasticity capital-labor vs. energy	Complementarity in production (c.f. Bourany 2020)
$\omega$	0.8	Fossil energy share in $e(\cdot)$	Fossil/Energy ratio
$\sigma_e$	2.0	Elasticity fossil-renewable	Slight substitutability & Study by Stern
$\delta$	0.06	Depreciation rate	Investment/Output ratio
$\bar{g}$	0.01★	Long run TFP growth	Conservative estimate for growth
$g_e$	0.01★	Long run energy directed technical change	Conservative / Acemoglu et al (2012)
$g_r$	-0.01★	Long run renewable price decrease	Conservative / Match price fall in R.E.
$\nu$	2★	Extraction elasticity of fossil energy	Cubic extraction cost
<i>Preferences &amp; Time horizon</i>			
$\rho$	0.03	HH Discount factor	Long term interest rate & usual calib. in IAMs
$\eta$	2.5	Risk aversion	
$n$	0.01★	Long run population growth	Conservative estimate for growth
$\omega_i$	1	Pareto weights	Uniforms / Utilitarian Social Planner
$T$	90	Time horizon	Horizon 2100 years since 2010

# Calibration

TABLE – Baseline calibration (★ = subject to future changes)

<i>Climate parameters</i>			
$\xi$	0.81	Emission factor	Conversion 1 <i>MTOE</i> $\Rightarrow$ 1 <i>MT CO<sub>2</sub></i>
$\zeta$	0.3	Inverse climate persistence / inertia	Sluggishness of temperature $\sim 11-15$ years
$\chi$	$2.1/1e6$	Climate sensitivity	Pulse experiment : 100 <i>GtC</i> $\equiv 0.21^\circ C$ medium-term warming
$\delta_s$	0.0014	Carbon exit from atmosphere	Pulse experiment : 100 <i>GtC</i> $\equiv 0.16^\circ C$ long-term warming
$\gamma^\oplus$	0.00234★	Damage sensitivity	Nordhaus' DICE
$\gamma^\ominus$	$0.2 \times \gamma^\oplus$ ★	Damage sensitivity	Nordhaus' DICE & Rudik et al (2022)
$\alpha^\tau$	0.2★	Weight historical climate for optimal temp.	Marginal damage decorrelated with initial temp.
$\tau^\star$	15.5	Optimal yearly temperature	Average spring temperature / Developed economies
<i>Parameters calibrated to match data</i>			
$p_i$		Population	Data – World Bank 2011
$z_i$		TFP	To match GDP Data – World Bank 2011
$\tau_i$		Local Temperature	To match temperature of largest city
$\mathcal{R}_i$		Local Fossil reserves	To match data from BP Energy review

## Sequential solution method

► Summary of the model :

- ODEs for states  $\{\mathbf{x}\} = \{w_{it}, \tau_{it}, \mathcal{R}_{it}, \mathcal{S}_t\}_{it}$
- Backward ODE for the costates  $\{\boldsymbol{\lambda}\} = \{\lambda_{it}^w, \lambda_{it}^\tau, \lambda_t^S, \lambda_{it}^{\mathcal{R}}\}_{it}$
- Non-linear equations (FOCs) for household controls  $\{\mathbf{c}_1\} = \{c_{it}, b_{it}, k_{it}\}_{it}$  and static demands for energy/capital  $\{\mathbf{c}_2\} = \{e_{it}^f, e_{it}^r, k_{it}\}_{it}$  and static supplies  $\{\mathbf{c}_3\} = \{e_{it}^x, \bar{e}_{it}^r\}_{it}$ .
- Market clearing as equation for prices  $\{\mathbf{q}\} = \{q_t^f, r_t^*\}_t$
- Existence and Uniqueness, c.f. Mean Field Game theory (Carmona-Delarue)

## Sequential solution method

### ► Summary of the model :

- ODEs for states  $\{\mathbf{x}\} = \{w_{it}, \tau_{it}, \mathcal{R}_{it}, \mathcal{S}_t\}_{it}$
- Backward ODE for the costates  $\{\boldsymbol{\lambda}\} = \{\lambda_{it}^w, \lambda_{it}^\tau, \lambda_t^S, \lambda_{it}^{\mathcal{R}}\}_{it}$
- Non-linear equations (FOCs) for household controls  $\{\mathbf{c}_1\} = \{c_{it}, b_{it}, k_{it}\}_{it}$  and static demands for energy/capital  $\{\mathbf{c}_2\} = \{e_{it}^f, e_{it}^r, k_{it}\}_{it}$  and static supplies  $\{\mathbf{c}_3\} = \{e_{it}^x, \bar{e}_{it}^r\}_{it}$ .
- Market clearing as equation for prices  $\{\mathbf{q}\} = \{q_t^f, r_t^*\}_t$
- Existence and Uniqueness, c.f. Mean Field Game theory (Carmona-Delarue)

### ► Global Numerical solution :

- Discretize agents (countries) space  $i \in \mathbb{I}$  with  $M$  and time-space  $t \in [t_0, t_T]$  with  $T$  periods
- Express as a large vector  $\mathbf{y} = \{\mathbf{x}, \boldsymbol{\lambda}, \mathbf{c}, \mathbf{q}\}$  in a large non-linear function

$$F(\mathbf{y}) = \mathbf{0}$$

- Solve for the large system with  $N = (N_{ind,vars} \times M + N_{agg,vars}) \times T$  unknowns and  $N$  equations with gradient-descent – Newton-Raphson methods.

## Sequential method : Pros and Cons

### ► Why use a sequential approach ?

- *Global approach* : Only need to follow the trajectories for  $i$  agents :
  - Arbitrary (!) number of dimension of *ex-ante* heterogeneity :  
*Productivity*  $z_i$  *Population*  $p_i$ , *Temperature scaling*  $\Delta_i$ , *Fossil energy cost*  $\bar{\nu}_i$ , *Energy mix*  $\epsilon_i, \omega_i, z_i^r$ ,  
*Local damage*  $\gamma_i^y, \gamma_i^u, \tau_i^*$ , *Directed Technical Change*  $z_i^e$
  - Potentially large dimensions of *ex-post* heterogeneity and aggregate state variables :  
*For now* : *Wealth*  $w_{it}$ , *temperature*  $\tau_{it}$ , *reserves*  $\mathcal{R}_{it}$ , *Carbon*  $S_t$   
*Extension with a large climate system as a proof of concept (e.g. Cai, Lontzek, Judd, 2013)*
  - Newton method & Non-linear solvers very efficient

### ► Why not :

- Numerical constraint to solve a large system of ODEs and non-linear equations :  
 ⇒ Constraint on  $N = (N_{ind,vars} \times M + N_{agg,vars}) \times T$ , so either  $M$  or  $T$  can't be too large
- Relying on numerical solvers/structure of the problem can be opaque
